Date of acceptance 26/3 / 2009

Abstract:

Five N-substituted poly diimides were prepared by two steps. First step was included the preparation of five N-substituted diamides by reaction of adipoyl chloride with different amines .The second step was involved reaction of diamides with poly acryloyl chloride to obtain five new poly diimides having different physical properties which may used in different applications.

Key words: diamides, polydiimides, polyacryloylchloride, adipoylchloride.

Introduction:-

Polyimides are very interesting groups of incredibly strong astoundingly heat and chemical resistant and other properties polymers. Their strength, heat and chemical resistance are so great that these materials often replace glass and metals, such as steel, in many demanding industrial application. Polymers are even used in many everyday applications.

Polyimides are step or condensation polymers derived from both aliphatic or aromatic dianhydries and diamines or their derivatives, and contain a hetero cyclicimide linkage in the repeating units.

Polyimides are often based on stiff aromatic backbones. The chemistry of polyimides is in itself a vast area with a large variety of monomers available to synthesis .However, there has been considerable debate on be various reaction mechanisms involved in different synthesis methods.

The properties of polyimides can be dramatically altered by minor variation in the structure. The subtle variations in the structures of the dianhydride and diamine components have a tremendous effect on the properties of the final polyimide[1-3].

The most widely practical procedure in polyimide synthesis is the two-step poly (amic acid) process. It involves reaction of dianhydride and a diamine at ambient conditions in a dipolar aprotic solvent to yield the corresponding poly (amic acid), which is then cyclized into the final polyimide of significant commercial importance such as kapton[4-6].

Other synthetic routes to polyimide were from diester-acids and diamine[7-9]. Another synthetic routes were from dianhydrides and diisocyanates

This research includes preparing of some N-substituted polydiimides through the reaction of acid chloride with amines to yield amides, then the prepared amide was reacted with poly acid chloride (poly acryloyl chloride), as shown in scheme -1-

Materials and Methods:

 Melting points were recorded by using Gallen Kamp MFB-600 capillary melting point apparatus.
 Infrared spectra were recorded on (FT-IR) infrared spectrophotometer as KBr disc in Baghdad University, College of Science, Chemistry Department.

*Prof. assistant, department of chemistry, college of science, university of Baghdad . **Teaching assistant, department of chemistry, college of science, university of Baghdad .

1-preparation of diamides (1-5) [10,11].

(0.1mol) of adipoyl chloride was diluted with 15ml of pure THF, and a solution of 0.2mol of pure amine in 15 -20ml of the same solvent was added until the odor of the acid chloride has disappeared; excess of the amine was not harmful. The mixture was Shaked with excess of dilute HCl to remove amine and its salts. The ethereal layer was washed with 5-10ml of water, and the solvent was evaporated. The amide was recrystallized from dilute ethanol.

2-preparation of poly [diacryl adip di N-substituted diimide] (6-10)[12].

A mixture of poly (acryloyl chloride) (0.2 mol)and diamide (0.1 mol)in dimethyl formamide (DMF) 25ml was refluxed for (8-10)hrs. After cooling the excess of solvent was removed under vacuum and the solid separated was filtered and purified by dissolving in suitable (DMF, DMSO) solvent and reprecipitating from another solvent such as (water, ethanol, acetone). Conversion of yielded polymers were (50-82%)

Results and discussion

Synthesis of some new poly Nsubstituted diimides were achieved from reaction of diamides and poly (acryloyl chloride).scheme-1-

Diamides were prepared through the reaction of adipoyl chloride with two moles of different amines in the same solvent.

Structures of diamides (1-5) were confirmed by physical properties which are listed in table (1).

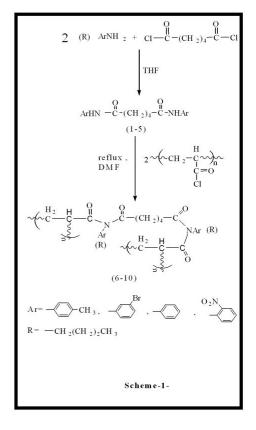

FTIR spectra showed the absorptions at region (3301-3247)cm⁻¹ due to υ (N-H) group, (1697-1643)cm⁻¹ for υ (C=O) amide ,(1595-1496)cm⁻¹ due to υ (C=C) aromatic, (3100-3031) cm⁻¹ for υ (C-H)aromatic ,(1414-1334) cm⁻¹ for υ (C-N),(2950-2860) cm⁻¹ due

to v(C-H)aliphatic and absorption of 1427 cm⁻¹ due to nitro group (NO₂).All these regions are listed in table(5).

The second step included the reaction of prepared diamide with two mole of poly (acryloyl chloride) in DMF (dimethyl formamide) at reflux temperature in (6-12)hrs.to produce polydiimid.

The structures of (6-10) were confirmed by physical properties which are listed in table (2).

FTIR spectra of compounds (6-10) showed disappearance of absorption band of -NH group at (3301-3247) cm⁻¹ which confirmed conversion to N-substituted imide group, and absorption at (1712-1643) cm⁻¹ due to v(C=O) imide, these and other absorptions are listed in table (6).

الخلاصة :-

تم تحضير خمس بوليمرات جديدة من نوع ثنائي الايمايد وتضمن هذا التحضير خطوتين ، الخطوة الاولى تحضير خمس مركبات من نوع ثنائي الامايدات من تفاعل كلوريد الاديبويل مع امينات مختلفة إما الخطوة الثانية فتضمنت مفاعلة ثنائي الامايد مع بوليمر كلوريد الاكريلويل ليعطي بوليمرات من نوع ثنائي الاميدات ذات مواصفات فيزيائية جديدة ممايسمح باستخدامها في تطبيقات مختلفة.
