Abstract:
In this article the unsteady magnetohydrodynamics oscillating flow of third order fluid with free stream velocity is proposed. It is found that the motion equation is controlled by five dimensionless parameters namely the coecostic parameter $\beta_4$, viscoelostic parameter $\Phi$, acceleration/deceleration $c$, suction/blowing $d$ and material constants $\alpha$. The effect of each of these parameters upon the velocity distribution is analysed.

Keywords: Unsteady flow, Magnetohydrodynamics(MHD), third order fluid, oscillating flow.

Introduction:
Fluid mechanics has fascinated many generations of scientists and engineers although many years of research have been devoted to the study of fluids of low molecular weight. The motion of any fluid is described by the equations of conservation of mass, momentum, and energy. Physically, the equation of continuity states that within a small fixed volume there can be no net rate of addition mass. The equation of momentum describes that the mass–time–acceleration of fluid element equals the sum of the pressure, viscous, and gravitational forces acting on the element, and the energy equation interprets that the temperature of a fluid element changes as it moves along with the fluid because of heat conduction and heat production by viscous heating [1,2]. In general, these three equations are used to describe the flow behavior but there are few situations under which the energy equation is not important for example, in sufficiently slow flows, viscous heating is not essential. In recent years, the flows of second order have been studied extensively and we refer to papers by Asghar. S, Hayat. Tand Siddiqui. A.M [3] which is studied moving boundary in a second-grade fluid. Which paper [4] discusses an increasing velocity amplitude of the oscillating porous plate it shows that in case of second-grade fluid a combination of suction/injection and decreasing/increasing velocity amplitude is possible as well. Later Ramano Murth. Ch.V and Kavitha. K.R. [5] studied flow of a second order fluid over an inclined porous plate under the influence of applied Magnetic field. In the present work, we discuss the viscous of non-Newtonian problem of an unsteady MHD third order fluid flow past an infinite oscillating porous plate. This work is modified of Muhammad R. mohyuddin [6] which discusses oscillating flow of second order and studied the effect of suction, acceleration and MHD. He observed the boundary layer decrease and the velocity is increase in case of suction $(d=-2,-1)$ but in case $(d=0.5, 1)$ the boundary layer becomes large, also it

*Department of mathematics, College of Science for Women, Baghdad University
**Department of mathematics, College of Science, Baghdad University
observed with difference that MHD parameter $\alpha$ is increased to 0.5.

**Formulation of the problem1**

Let us assume that the $x$-axis is parallel to the oscillating porous plate and the $y$-axis is perpendicular to it, also we will assume that the third order fluid initially at rest thus the velocity field is given by

$$\mathbf{V} = [u(y, t), v_0, 0]$$

and $v_0 > 0$ are correspondents to suction and blowing velocities respectively. For $t > 0$ plate is moved period according to

$$u(0, t) = u(t) = u_0 \left(2 - i \omega t\right)$$

where $u_0 > 0$, $t > 0$, $\beta = \text{constant} \neq 0$.

In this case the continuity and motion equations are

$$\nabla \cdot \mathbf{V} = 0 \quad \text{... (1)}$$

$$\rho \left(\frac{\partial \mathbf{V}}{\partial t} + \mathbf{V} \cdot \nabla \mathbf{V}\right) = -\nabla P + \nabla \tau + \mathbf{J} \times \mathbf{B} \quad \text{... (2)}$$

Where $\mathbf{J}$ is the electric current density, $\mathbf{B}$ is the magnetic field, $\sigma$ is the electrical conductivity of the fluid and the stress tensor $\tau$ is defined by

$$\tau = -P I + \mu \left(A_1 + \alpha_1 A_2 + \alpha_2 A_1^2 + \beta_3 (\text{tr}A_1) A_1\right) \quad \text{... (4)}$$

Where $P$ is the pressure, $\mu$ is the dynamic viscosity, $I$ is the identity tensor, $\alpha_i$, $i = 1, 2$ and $\beta_3$ are the material constants [7]. The Rivlin-Ericksen tensors are

$$A_1 = \nabla \nabla + \left(\nabla \nabla\right) \quad \text{... (5)}$$

$$A_2 = \frac{\partial A_1}{\partial t} + \nabla \cdot \frac{\partial \nabla}{\partial x} + A_1 \nabla \nabla + \left(\nabla \nabla\right) A_1 \quad \text{... (6)}$$

In which the prime sign represents the transpose of matrix and $\nabla$ is the gradient operator. In addition to that we will assume $v = \text{constant} = v_0$ and the follow constraints are imposed $\mu \geq 0$.

$$\alpha_1 \geq 0, |\alpha_1 + \alpha_2| \leq \sqrt{2 \mu \beta_3} \quad \beta_3 \geq 0.$$ 

Now, by using equations (3), (4) and (5) the motion equation (2) reduces to

$$\left(\frac{\partial^2 u}{\partial y \partial t} + \nu \frac{\partial^2 u}{\partial y^2}\right) = \frac{\partial u}{\partial y} + \frac{\alpha_1}{\rho} \frac{\partial^2 u}{\partial y \partial t} + \frac{\partial \mathbf{V}}{\partial t} \cdot \nabla \mathbf{V} \quad \text{... (6)}$$

Which corresponds to the following conditions $u(0, t) = u_0 e^{(2 - i \omega t)}$, $u(y, 0) = u_0$.

Integrating equation (6) with respect to $y$, we get

$$\left(\frac{\partial u}{\partial t} + v_0 \frac{\partial u}{\partial y}\right) = \frac{\partial^2 u}{\partial y^2} + \frac{\alpha_1}{\rho} \frac{\partial^2 u}{\partial y \partial t} + \mathbf{J} \times \mathbf{B} \quad \text{... (7)}$$

Where $n = \frac{\alpha_2 v_0}{\rho} = \frac{\mu}{\rho}$ and $k(t)$ is the integration constant.

If we assume that $u(y, t) \rightarrow f_1(t)$ as $y \rightarrow \infty$, then from (7) we have

$$k(t) = \frac{\partial f_1}{\partial t} + nf_1(t)$$

Equation (7) can be written as

$$\frac{\partial u}{\partial t} + v_0 \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} + \frac{\alpha_1}{\rho} \frac{\partial^2 u}{\partial y \partial t} + \mathbf{J} \times \mathbf{B} \quad \text{... (8)}$$

where $f_1$ is the free stream velocity and will be solved subject to the boundary and initial conditions

$$u(0, t) = u(t) = u_0 e^{(2 - i \omega t)}, \quad u(\infty, t) = f_1, \quad u(y, 0) = u_0 \quad \text{... (9)}$$

To give some physical meaning for the problem we assume that $f_1 = u_0 = \text{constant}$ then equation (8) reduce to

$$\frac{\partial^2 u}{\partial y^2} + \mathbf{J} \times \mathbf{B} = \left(u_0 - u\right) n \quad \text{... (10)}$$

Which may be written as

$$\left(\frac{\partial^2 u}{\partial y^2} - \frac{\partial \mathbf{V}}{\partial t} \cdot \nabla \mathbf{V} + \mathbf{J} \times \mathbf{B}\right) = \alpha (1 - f) \quad \text{... (11)}$$

Where

$$n = \frac{\omega^2 \tau c}{\sqrt{2 \nu \omega c}}$$
\[ \frac{\omega}{2\nu} \frac{\partial}{\partial \tau} \left( \beta = \frac{a}{\rho} \right), \beta_4 = \frac{6u_0^2}{4\nu} \left( \alpha - \frac{\beta_2}{\rho \beta} \right)^2 \]

\[ \alpha = \frac{\sigma \beta_2}{\beta_4} \]

and the boundary conditions are \( f(0, \tau) = f(\tau) = e^{(\tau-i)\tau}, f(\infty, \tau) = 1, f(\eta, 0) = 1 \)

Equation (11) is a nonlinear partial differential equation of third order and its solution is given in the next section.

**Solution of the problem**

Let \( g = 1 - f \) then the equation (11) reduces to

\[ \frac{\partial^2}{\partial \tau^2} \left( \frac{\partial g}{\partial \eta} \right) + \frac{\partial}{\partial \eta} \left( \frac{\partial g}{\partial \eta} \right) - \beta_4 \left( \frac{\partial^2 g}{\partial \eta^2} \right)^2 = \alpha g \]

..(12)

and the boundary conditions become

\[ g(0, \tau) = 1, g(\eta, 0) = 0 \]

To solve equation (12) we expand \( g \) in terms of \( \beta_4 \) and as follows

\[ g = g_1 + \beta_4 g_2 \]

Note that, we use this expansion to cover the results obtained by [4], where \( g_1 \) is corresponding to his solution [eq. (10)]

\[ \nu \frac{\partial^2 u}{\partial \eta^2} - \nu \frac{\partial^2 u}{\partial y^2} + n \frac{\partial u}{\partial y} = 0 \]

Putting the last expression into equation (12), we obtain the following two equations:

\[ \frac{\partial^2}{\partial \tau^2} \left( \frac{\partial g}{\partial \eta} \right) + \frac{\partial}{\partial \eta} \left( \frac{\partial g}{\partial \eta} \right) - \beta_4 \left( \frac{\partial^2 g}{\partial \eta^2} \right)^2 = \alpha g \]

..(15)

To solve equation (15), substitute \( g(\eta, \tau) = h_1(\eta) e^{(\tau-i)\tau} \) into (15) we get an ordinary differential equation of the second order, which is

\[ (\Phi (c - i) + \frac{1}{2}) \frac{\partial^2 h_1}{\partial \eta^2} - \sqrt{2} \beta_4 \frac{\partial h_1}{\partial \eta} - \frac{1}{2} \frac{\partial^2 h_1}{\partial \eta^2} = \alpha g \]

..(17)

Similarly, to solve equation (16), let \( g(\eta, \tau) = h_2(\eta) e^{3(c-i)\tau} \) and substitute this expression into equation (16), we obtain

\[ \left( 3\Phi (c - i) + \frac{1}{2} \right) \frac{\partial^2 h_2}{\partial \eta^2} - \sqrt{2} \beta_4 \frac{\partial h_2}{\partial \eta} - (3(c - i) + \alpha)h_2 = \frac{\partial^2 h_1}{\partial \eta^2} \]

..(18)

By solving equations (17) and (18), it is found that

\[ g = e^{0.5(a - (a^2 + 4b))} \]

\[ a^4 - 4a^2b - 2b^2 + a^3 \sqrt{a^2 + 4b + 2ab} \sqrt{a^2 + 4b} \]

\[ e^{-(3b + 3c + b + 3r - \sqrt{-4q + r^2})} \]

\[ a^2 + 36b + 4q + 6\sqrt{a^2 + 4b} - 6a(3\sqrt{a^2 + 4b + r}) \]

Finally, by substituting \( f = 1 - g \) in the last equation we found that

\[ f = 1 - \frac{a^2 - 4a^2b - 2b^2 + a^3 \sqrt{a^2 + 4b + 2ab} \sqrt{a^2 + 4b} \}

\[ e^{-(3b + 3c + b + 3r - \sqrt{-4q + r^2})} \]

\[ a^2 + 36b + 4q + 6\sqrt{a^2 + 4b} - 6a(3\sqrt{a^2 + 4b + r}) \]

Where

\[ a = d\sqrt{2} / (\Phi (c - i) + 0.5); b = a + c - i; \]

\[ r = d\sqrt{2} / (\Phi (c - i) + 0.5); \]

\[ q = (a + i - c) / (\Phi (c - i) + 0.5); \]

**Results and Discussion**

In this section we study the effect of each parameter upon the velocity distribution to do this, all figures are plots for non-dimensional velocity \( f \) against the non-dimensional variable \( \eta \). The solution for velocity component \( f \) is plotted in all figures for different values of \( \Phi, \beta_4, a, d, c \) and for fixed time \( \pi/4 \) as a function of the suction. The values of \( \Phi, \beta_4, a, d, c, \alpha \) are respectively

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]

\[ \Phi = [0.01, 0.07, 1, 2], \beta_4 = [0.01, 0.03, 0.05, 0.07], d = [-2, -1, \]

\[ -0.5, 0, 0.5, 1, 2], c = [0.01, 0.03, 0.05, 0.07], \alpha = [0.01, 0.03, 0.05, 0.07]; \]
0.5,0], c=[0, 0.2, 0.3, 0.5] and α is constant (α=0.1)

**Effect β₄ on velocity**

Figs (1) illustrate the effect of coecostic parameter β₄ upon the velocity. In case of c=0 (acceleration) and the blowing parameter d =-0.5 ,we note that as β₄ increase, the velocity decrease. Fig (2) shows the effect of β₄ where c=-0.5 (deceleration) and d=0 as the same as effect in fig (1).

**Effect Φ on velocity**

Figs (3,4) illustrate the effect of viscoelostic parameter Φ upon the velocity , its noted that with increase in Φ the velocity decrease. In fig(3) where c=-0.5,d=0 its observed that with increase of Φ from 0.01 to 0.07 the velocity increase , when 0.07 < Φ ≤ 1 the velocity increase .For Φ > 1 the velocity start to decrease. Fig (4)also shows the similar results in fig(3).

**Effect c and d on velocity**

Fig (5) shows that as c=-0.5, β₄=0 , Φ =0.7 the velocity decrease when increase of d. In fig (6) also the similar results in fig(5)with difference the velocity range decrease from 4.5 to1 . Figs (7,8) show the effect c on
velocity, it observed that as $c$ increase the velocity decrease

Fig(5) distribution velocity for $d=[-2,-0.5,-1.0]$, $c=-0.5$; $\beta_4=0.7$, $\alpha=0.1$, $\Phi=0$, $\tau=\pi/4$

Fig(7) distribution velocity for $c=[0,0.2,0.3,0.5]$, $d=0.5$, $\beta_4=0$, $\alpha=0.1$, $\Phi=0$, $\tau=\pi/4$

Fig(6) distribution velocity for $d=[-2,-0.5,-1.0]$, $c=0.5$; $\beta_4=0$, $\alpha=0.1$, $\Phi=0$, $\tau=\pi/4$

Fig(8) distribution velocity for $c=[0,0.2,0.3,0.5]$, $d=-0.5$, $\beta_4=0$, $\alpha=0.1$, $\Phi=0$, $\tau=\pi/4$
