## Approximated Methods for Linear Delay Differential Equations Using Weighted Residual Methods

## Abdul Khaliqe Ewaid Mizel\*

Date of acceptance 2/10/2007

### Abstract:

The main work of this paper is devoted to a new technique of constructing approximated solutions for linear delay differential equations using the basis functions power series functions with the aid of Weighted residual methods (collocations method, Galerkin's method and least square method).

Keywords: linear Delay Differential Equation ; Weighted residual methods.

## **Introduction:**

The delay differential ordinary equation "DDE" is an equation in an unknown function y (t) and some of its derivatives are evaluated at arguments that differ in any of fixed number of values T, T, T

values  $\tau_1, \tau_2, \ldots, \tau_n$ .

The general form of the n-th order DDE is given by

 $F(t, y(t), y(t - \tau_1), ..., y(t - \tau_k), y'(t), y'(t - \tau_1), ..., y'(t - \tau_k),$  $y^n(t), ..., y^n(t - \tau_k)) = 0$ 

....(1) Where F is a given function and  $\tau_1, \tau_2, \ldots, \tau_k$  are given fixed positive numbers called the "time delay", [1].

In some literature, equ. (1) is called a differential equation with deviating argument [1,2], or an equation with time lag [3], or a differential difference equation ,or a functional differential equation [4].

The general linear first order delay differential equation with constant coefficients can be presented in the form

 $a_0 y'(t) + a_1 y'(t-\tau) + b_0 y(t) + b_1 y(t-\tau) = g(t) \dots (2)$ 

where g(t) is a given continuous function and  $\mathcal{T}$  is a positive constant and  $a_0, a_1, b_0, b_1$  are constants.

We can distinguish between three types of delay differential equations, which are:

1. Retarded delay differential equation, which is obtained when:  $(b_i \neq 0, a_i = 0)$  in equ.(2) the delay comes

in y only and (2) takes the

Form:  $a_0 y'(t) + b_0 y(t) + b_1 y(t - \tau) = g(t)$ 

2. Neutral delay differential equation, which is obtained when:

 $(a_1 \neq 0, b_1 = 0)$  in equ.(2) the delay comes in y' only and (2) takes the form:  $a_1 y'(t) + a_2 y'(t - \tau) + b_2 y(t) = a(t)$ 

- $a_0 y'(t) + a_1 y'(t-\tau) + b_0 y(t) = g(t)$
- 3. Mixed delay differential equation, (sometimes called advanced type), which is obtained where  $(a_1 \neq 0, b_1 \neq 0)$ , which means a combination of the previous two types.

#### Weighted Residual Methods:

We present these methods by considering the following functional equation [5].  $L [v(x)] = 2(x) - x \in D$  (2)

 $L[y(x)] = g(x) \quad x \in D \quad ...(3)$ 

Where L denotes an operator which maps a set of functions Y in to a set G such that  $y \in Y$ ,  $g \in G$  and D is a prescribed domain.

The epitome of the expansion method is to approximate the solution y(x) of equ.(3) by the form

$$y_N(x) = \sum_{i=0}^N c_i \psi_i(x)$$
 .... (4)

Where the parameters  $c_i$  and the functions  $\psi_i(x)$  are chosen in our work as:

## The Power Series Functions: This basis function can be defined as

$$E(x) = L[y_N(x)] - g(x) \dots (5)$$

The residual E (x) depends on x as well as on the way that the parameter  $c_i$  are chosen.

It is obvious that when E(x) = 0, then the exact solution is obtained which is difficult to be achieved, therefore we shall try to minimize E(x) in some sense. In the weighted residual method the unknown parameters  $c_i$  are chosen to minimize the residual E (x) by setting its weighted integral equal to zero, i.e.

$$\int_{D} w_{j} E(x) dx = 0 \qquad j = 0, 1, \dots, N \qquad \dots (6)$$

Where  $w_j$  is prescribed weighting function, the technique based on (6) is called weighted residual method. Different choices of  $w_j$  yield different methods with different approximate solutions.

The weighted residual methods that will be discussed in this work are:

## **1.** Collocation Method

- 2. Galerkin's Method
- 3. Least Square Method

## **<u>1 Collocation Method:</u>**

It is a simple method for obtaining a linear approximation  $y_N$  [7] In this method the weighting function is

chosen to be

$$w_j = \delta(x - x_j)$$
 .... (7)  
Where the fixed points  $x_j \in D$ ,  $j = 0,1,...,N$  are called collocation points. Here Dirac's delta function  $\delta(x - x_j)$  is defined as

$$\delta(x - x_j) = \begin{cases} 1 & \text{if } x = x_j \\ 0 & \text{else} \end{cases}$$

Inserting equ.(7) in equ.(6) gives

$$\int_{D} w_{j} E(x_{j}) dx = \int_{D} \delta(x - x_{j}) E(x_{j}) dx = \int_{x_{j}}^{x_{j}^{+}} \delta(x - x_{j}) E(x_{j}) dx$$
$$= E(x_{j}) \int_{x_{j}}^{x_{j}^{+}} \delta(x - x_{j}) dx = E(x_{j}) = 0 \quad j = 0, 1, ..., N$$
$$\dots (8)$$

Equ.(8) will provide us with (N+1) simultaneous equations to determine the parameters  $c_i$ 's. Moreover the distribution of collocation points on D is arbitrary, however, in practice we distribute the collocation points uniformly on D.

## 2 Galerkin's Method: [7]

Galerkin method is the most efficient of the weighted residual methods. This method makes the residual E (x) of equ. (6) orthogonal to (N+1) given linearly independent function on the domain D.

The weighting function w<sub>j</sub> is defined as:

$$w_j(x) = \frac{\partial y_N(x)}{\partial c_j}$$
  $j = 0, 1, ..., N$ 

where  $y_N(x)$  is the approximate solution of the problem, then equ.(6) becomes.

$$\int_{D} \frac{\partial y_{N}(x)}{\partial c_{j}} E(x) dx = 0 \qquad j = 0, 1, \dots, N$$
  
...(9)

and will provide (N+1) simultaneous equations for determination of  $c_0$ ,  $c_1$ , ...,  $c_N$ .

#### <u> 3 Least Square Method:[7]</u>

In this method weighting function w<sub>i</sub> is defined as:

$$w_j(x) = \frac{\partial E(x)}{\partial c_j}$$
  $j = 0, 1, ..., N$ 

and due to equ.(6) we have

$$\int_{D} \frac{\partial E(x)}{\partial c_{j}} E(x) dx = 0 \qquad j = 0, 1, \dots, N$$
$$\dots (10)$$

then the square of the error on the domain D is

$$J = \int_{D} \left[ E(x) \right]^2 dx$$

Now, we compute the derivatives

$$\frac{\partial J}{\partial c_j} = 2 \int_D E(x) \frac{\partial E(x)}{\partial c_j} dx \qquad j = 0, 1, \dots, N$$
  
...(11)

it implies from equ.(10),(11) that

$$\frac{\partial J}{\partial c_j} = 2 \int_D E(x) \frac{\partial E(x)}{\partial c_j} dx = 0 \qquad j = 0, 1, \dots, N$$

Therefore J is stationary and the square of residual E(x) attains its minimum

## Solution of Linear DDE s By Weighted Residual Methods:

The general form nth order nonhomogenous non linear delay differential equations is

$$y^{n}(x) + \sum_{p=0}^{n} a_{p} y^{p}(x) + \sum_{m=0}^{n-1} b_{m} y^{m}(x-\tau) + \sum_{l=0}^{n} d_{l} y^{l}(x-\tau) = g(x)$$
.... (12)

where  $\mathcal{T}$  is a prescribed constant and  $a_p$ ,  $b_m$  and  $d_l$  are constants with initial condition

$$y(0) = y_0, \quad y'(0) = y_1, \dots, y^{(n-1)}(0) = y_{n-1}, \quad y^n(0) = y_n$$

Using operator forms this equation can be written as

$$L[y] = g(x) \dots (13)$$

where the operator L is defined as

$$L[y] = y^{n}(x) + \sum_{p=0}^{n} a_{p} y^{p}(x) + \sum_{m=0}^{n-1} b_{m} y^{m}(x-\tau) + \sum_{l=0}^{n} d_{l} y^{l}(x-\tau)$$

The unknown function y(x) is approximated by the form

$$y_N(x) = \sum_{j=0}^N c_j \psi_j(x)$$
 ...(14)

Substituting equ.(14) in equ.(13) we get

$$L[y_N] = g(x) + E_N(x)$$

Where

$$L[y_N(x)] = y_N^n(x) + \sum_{p=0}^n a_p y_N^p(x) + \sum_{m=0}^{n-1} b_m y_N^m(x-\tau) + \sum_{l=0}^n d_l y_N^l(x-\tau)$$

Which we have the residue equation  $E_N(x) = L[y_N(x)] - g(x) \dots (15)$ 

Substituting the equ.(14) in equ.(15), we get

$$E_{N}(x) = L \left[ \sum_{j=0}^{N} c_{j} \psi_{j} \right] - g(x) = \sum_{j=0}^{N} c_{j} L \left[ \psi_{j}(x) \right] - g(x)$$
  
...(16)

Evidently from equ.(6) that

$$\int_{D} w_{j} E_{N}(x) = 0 \qquad ... (17)$$

Inserting equ.(16) in equ.(17) yields

$$\int_{D} w_{j} \left( \sum_{j=0}^{N} c_{j} L[\psi_{j}(x)] - g(x) \right) = 0$$
  
$$\sum_{j=0}^{N} c_{j} \int_{D} w_{j} L[\psi_{j}(x)] = \int_{D} w_{j} g(x) \quad \dots (18)$$

Where

$$L(\psi_{j}(x)) = \psi_{j}^{n}(x) + \sum_{p=0}^{n} a_{p} \psi_{j}^{p}(x-\tau) + \sum_{m=0}^{n-1} b_{m} \psi_{j}^{m}(x-\tau) + \sum_{l=0}^{n} d_{l} \psi_{j}^{l}(x-\tau)$$
  
For j=0,1,...,N ... (19)

Introducing matrix k and vector h as

$$k_{ji} = \int_{D} w_{j} L(\psi_{i}(x)) dx \qquad i = 0, 1, ..., N \qquad ... (20)$$
  
$$h_{j} = \int_{D} w_{j} g(x) dx \qquad j = 0, 1, ..., N$$

We can write equ.( 18) in compact form (21)

$$K C = H \qquad \dots (21)$$
  
Where

$$C = \begin{pmatrix} c_0 \\ c_1 \\ \vdots \\ c_N \end{pmatrix}$$

Finally, we have N+1 linear equations (21) for determing N+1 coefficient  $c_0$ ,  $c_1$ , ...,  $c_N$ .

## <u>1 UsingCollocation Method:</u>

In this method we choose the collocation points  $x_0$ ,  $x_1$ , ...,  $x_N$  in the closed interval  $[t_0, t_0 + \tau]$ , such that

$$x_i = 1 / (i+1)$$
  $i = 0, 1, ..., N$ 

Hence we have

$$E_{N}(x_{i}) = 0$$
  $i = 0, 1, ..., N$ 

This leads to

$$\sum_{j=0}^{N} L(\psi_j(x_i)) c_j = g(x_i) \quad i = 0, 1, \dots, N \quad \dots (22)$$

Hence equ.(22) can be seen as a system of (N+1) equations in the (N+1) unknown  $c_i$ , j = 0, 1, ..., N

$$\begin{array}{c} L(\psi_{0}(x_{0})) \ L(\psi_{1}(x_{0})) \ \dots \ L(\psi_{N}(x_{0})) \\ L(\psi_{0}(x_{1})) \ L(\psi_{1}(x_{1})) \ \dots \ L(\psi_{N}(x_{1})) \\ \vdots \\ L(\psi_{0}(x_{N})) \ L(\psi_{1}(x_{N})) \ \dots \ L(\psi_{N}(x_{N})) \end{array} \right] \begin{bmatrix} c_{0} \\ c_{1} \\ \vdots \\ c_{N} \end{bmatrix} = \begin{bmatrix} g(x_{0}) \\ g(x_{1}) \\ \vdots \\ g(x_{N}) \end{bmatrix} \\ \vdots \\ g(x_{N}) \end{bmatrix}$$

$$\begin{array}{c} \dots \ (23) \end{array}$$

A computationally efficient way to calculate the value  $c_j$  is by solving the sysetm

#### KC=H

#### Where

$$K = \begin{bmatrix} L(\psi_{0}(x_{0})) \ L(\psi_{1}(x_{0})) \ \dots \ L(\psi_{N}(x_{0})) \\ L(\psi_{0}(x_{1})) \ L(\psi_{1}(x_{1})) \ \dots \ L(\psi_{Nn}(x_{1})) \\ \vdots \\ L(\psi_{0}(x_{N})) \ L(\psi_{1}(x_{N})) \ \dots \ L(\psi_{N}(x_{N})) \end{bmatrix}, C = \begin{bmatrix} c_{0} \\ c_{1} \\ \vdots \\ c_{N} \end{bmatrix}, H = \begin{bmatrix} g(x_{0}) \\ g(x_{1}) \\ \vdots \\ g(x_{N}) \end{bmatrix}$$
  
... (24)

For the coefficient  $c_j \circ s$  which satisfies equ.(14) the approximate solution of equ.(12) will be given.

#### <u>Algorithm (WC)</u>

The approximate solution for DDE using collocation method can be briefly introduced in following steps.

Step 1: Put  $x_i = 1 / (i+1)$  for i = 0, 1, ..., N.

Step 2: Select  $\psi_j$  for j = 0, 1, ...,N.

Step 3: Compute  $L(\psi_j(x_i))$  using equ.(19) for i = 0, 1, ..., N.

Step 4:Compute the matrices k and H by using equ.(24).

Step 5: Solve the system (23) for coefficient  $c_i \circ s$ .

Step 6: Substitute  $c_j \circ s$  in transforming form to obtain the approximate solution of y(x).

## <u> 2 Using Galerkin Ós Method:</u>

It is a simple technique for obtaining a linear approximation  $y_N$ , the weight function  $w_j$  in equ.(6) is defined as [7]

$$w_j(x) = \frac{\partial y_N(x)}{\partial c_j}$$
  $i = 0, 1, ..., N$ 

now since

$$y_N(x) = \sum_{i=0}^N c_i \psi_i$$

Therefore

$$w_j(x) = \frac{\partial}{\partial c_j} \sum_{i=0}^N c_i \psi_i = \psi_j$$
,  $j = 0, 1, \dots, N$ 

... (25)

Substituting equ.( 25) in equ.( 18) we get

$$\sum_{i=0}^{N} c_{j} \psi_{j} L(\psi_{j}) = \int_{D} \psi_{j} g(x), \quad j = 0, 1, \dots, N$$

The linear system (21) becomes

$$\begin{bmatrix} \int_{D}^{W_{0}} \mathcal{L}(\psi_{0}) dx & \int_{D}^{W} \mathcal{L}(\psi_{1}) dx & \dots & \int_{D}^{D} \mathcal{L}(\psi_{N}) dx \\ \int_{D}^{W_{1}} \mathcal{L}(\psi_{0}) dx & \int_{D}^{W} \mathcal{L}(\psi_{1}) dx & \dots & \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots & & \\ \int_{D}^{W} \mathcal{L}(\psi_{0}) dx & \int \psi_{N} \mathcal{L}(\psi_{1}) dx & \dots & \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} \begin{bmatrix} c_{0} \\ c_{1} \\ \vdots \\ c_{N} \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{0}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \\ \vdots \\ \int_{D}^{W} \mathcal{L}(\psi_{N}) dx \end{bmatrix} = \begin{bmatrix} \int_{$$

Hence solving the system KC = H for coefficient  $c_j$  s.

Where  $K = \begin{bmatrix} \int_{D}^{W_{0}L(\psi_{0})dx} \int_{D}^{W_{0}L(\psi_{1})dx} \dots \int_{D}^{W_{0}L(\psi_{N})dx} \\ \int_{D}^{W_{1}L(\psi_{0})dx} \int_{D}^{W_{1}L(\psi_{1})dx} \dots \int_{D}^{W_{1}L(\psi_{N})dx} \\ \vdots \\ \int_{D}^{W_{N}L(\psi_{0})dx} \int_{V}^{W_{N}L(\psi_{1})dx} \dots \int_{D}^{W_{N}L(\psi_{N})dx} \end{bmatrix}, \dots (27)$   $C = \begin{bmatrix} c_{0} \\ c_{1} \\ \vdots \\ \vdots \end{bmatrix} \qquad \& \quad H = \begin{bmatrix} \int_{D}^{W_{0}gdx} \\ \vdots \\ f & \vdots \\ f & \vdots \end{bmatrix}$ 

Substitute the coefficient in equ.(13) to obtain approximate solution.

#### <u>Algorithm (WG)</u>

This method can be summarized in the following steps

Step 1: Select  $\psi_i$  for  $j = 0, 1, \dots, N$ .

Step 2: Compute  $L(\psi_j)$  by using equ. (19) for j = 0, 1, ..., N.

Step 3: Compute the matrices K and H by using equ.( 27).

Step 4: Solve the system (26) for coefficients  $c_i \circ s$ .

Step 5:Substitute  $c_j$  s in transforming form to obtain the approximate solution of y(x).

#### **3Using Least Square Method:**

The standard least squares approach is to attempt to minimize the sum of the squares of the residual at each point in the domain D.

Here this minimization of [7]

$$I(\bar{c}) = \frac{1}{2} \int_{D} [E_{N}(x)]^{2} dx$$
  
here  $\bar{c} = (c_{0}, c_{1}, \dots, c_{N})$ 

Where

This technique is to solve the (N+1)

normal equation given by a  $\partial F(r)$ 

$$\frac{\partial I}{\partial c_i} = \int_D E_n(x) \frac{\partial E_n(x)}{\partial c_i} dx = 0 \quad , \quad i = 0, 1, \dots, N$$

Substituting eq.(18), yields

$$\int_{D} \sum_{j=0}^{N} c_{j} L(\psi_{i}(x)) L(\psi_{j}(x)) dx = \int_{D} L(\psi_{i}(x)) g(x) dx$$
  
$$i = 0.1...N$$

The linear system (21) becomes

$$\begin{bmatrix} \int_{D} L(\psi_{0}) L(\psi_{0}) dx \int_{D} L(\psi_{1}) L(\psi_{1}) dx & \dots & \int_{D} L(\psi_{0}) L(\psi_{n}) dx \\ \int_{D} L(\psi_{1}) L(\psi_{0}) dx \int_{D} L(\psi_{1}) L(\psi_{1}) dx & \dots & \int_{D} L(\psi_{1}) L(\psi_{n}) dx \\ \vdots \\ \int_{D} L(\psi_{n}) L(\psi_{0}) dx \int L(\psi_{n}) L(\psi_{1}) dx & \dots & \int_{D} L(\psi_{n}) L(\psi_{n}) dx \end{bmatrix} \begin{vmatrix} c_{0} \\ c_{1} \\ \vdots \\ \int_{D} L(\psi_{n}) dx \end{vmatrix} = \begin{bmatrix} \int_{D} L(\psi_{0}) g dx \\ \int_{D} L(\psi_{1}) g dx \\ \vdots \\ \int_{D} L(\psi_{n}) g dx \end{vmatrix}$$

$$\vdots \\ \int_{D} L(\psi_{n}) L(\psi_{0}) dx \int L(\psi_{n}) L(\psi_{1}) dx & \dots & \int_{D} L(\psi_{n}) L(\psi_{n}) dx \end{vmatrix}$$

#### Where

$$K = \begin{bmatrix} \int_{D}^{C} L(\psi_{0})L(\psi_{0})dx & \int_{D}^{D} L(\psi_{0})L(\psi_{1})dx & \dots & \int_{D}^{D} L(\psi_{0})L(\psi_{n})dx \\ \int_{D}^{D} L(\psi_{1})L(\psi_{0})dx & \int_{D}^{D} L(\psi_{1})L(\psi_{1})dx & \dots & \int_{D}^{D} L(\psi_{1})L(\psi_{n})dx \\ \vdots & & \\ \int_{D}^{C} L(\psi_{n})L(\psi_{0})dx & \int L(\psi_{n})L(\psi_{1})dx & \dots & \int_{D}^{D} L(\psi_{n})L(\psi_{n})dx \end{bmatrix}$$
$$C = \begin{bmatrix} c_{0} \\ c_{1} \\ \vdots \\ c_{N} \end{bmatrix} & \& \quad H = \begin{bmatrix} \int_{D}^{D} L(\psi_{0})gdx \\ \vdots \\ L(\psi_{n})gdx \\ \vdots \\ \int_{D}^{D} L(\psi_{n})gdx \end{bmatrix}$$
$$\dots (29)$$

Hence the system of N+1 linear equations with N+1 unknown N+1 coefficients  $c_0$ ,  $c_1$ , ...,  $c_N$  will construct.

By solving this system, the values of cis will be found and then substituted in equ.(13) to obtain the approximate solution.

#### Algorithm (WL)

This method can be summarized in the following steps

Step 1: Select  $\psi_{i}$  for j = 0, 1, ...,N.

Step 2: Compute  $L(\psi_i) \& L(\psi_i)$  by using equ.(19) for i = 0, 1, ..., N, j =0, 1, ...., N.

Step 3: Compute the matrices K and H by using equ.(29).

Step 4: Solve the system (28) for coefficients ciós.

Step 5: Substitute  $c_i \circ s$  in equ.(13) to obtain the approximate solution.

#### **Transforming the Interval:**

Sometimes it is necessary to take a problem state on interval [a, b], then we can convert the variable so that the problem is reformulated on [-1, 1], as follows  $x = \frac{(b-a)t+b+a}{2}$ ,  $dx = \frac{(b-a)}{2}dt$ so that Then  $\int_{-\infty}^{b} g(x) dx = \frac{b-a}{2} \int_{-\infty}^{1} g\left(\frac{(b-a)t+b+a}{2}\right) dt$ Conversely, transform the limits of integration from [-1, 1] to [a, b] using  $t = 2\left(\frac{x-a}{b-a}\right) - 1,$ So that  $dt = \frac{2}{b-a}dx$ 

Then

$$\int_{a}^{b} g(t)dt = \frac{2}{b-a} \int_{a}^{b} g\left(2\left(\frac{x-a}{b-a}\right) - 1\right) dx$$

## Test Example: <u>Example (1):</u>

Consider the following first order delay differential equation of retarded type:

$$y'(t) = -2y(t) + y(t - \frac{\pi}{2}) + \sin t$$
  $t \ge 0$ 

With initial function

$$y(t) = -0.25 \qquad -0.25 \le t \le 0$$
  
Which has exact solution

Which has exact solution

$$y(t) = -\frac{1}{4}\cos t + \frac{1}{4}\sin t \qquad 0 \le t \le \frac{1}{4}$$

Assume the approximate solution in the form

$$y_N(t) = \sum_{j=1}^N a_j \psi_j (2x-1)$$

Table (1) lists the least square errors obtained by running the programs for algorithms (WC, WG and WL) with different values to find approximate solution of above equation.

# Table (1) The approximated values of y(t) against the exact value for N=5 and $\Delta$ t=10

t	Exact	Power series function			
		WC	WG	WL	
0.0	-0.2500	-0.2500	-0.2500	-0.2500	
0.1	-0.2238	-0.2238	-0.2238	-0.2238	
0.2	-0.1953	-0.1954	-0.1953	-0.1953	
0.3	-0.1650	-0.1650	-0.1650	-0.1650	
0.4	-0.1329	-0.1330	-0.1329	-0.1329	
0.5	-0.0995	-0.0996	-0.0995	-0.0996	
0.6	-0.0652	-0.0653	-0.0652	-0.0652	
0.7	-0.0302	-0.0303	-0.0302	-0.0302	
0.8	0.0052	0.0051	0.0052	0.0051	
0.9	0.0404	0.0403	0.0404	0.0404	
1.0	0.0753	0.0752	0.0753	0.0753	
L.S.E.		2.3e-3	2.2e-4	3.0e-3	

**Example** (2): Consider the following first order delay differential equation of neutral type:

$$y'(t) = 1 - y'(t - \frac{y(t)^2}{4})$$

With initial function

y(t) = 1 + t  $0 \le t \le 1$ Which has exact solution

$$y(t) = 1 + \frac{t}{2} + \frac{t^2}{4}$$
  $0 \le t \le 1$ 

Assume the approximate solution as in the form

$$y_N(t) = \sum_{j=1}^N a_j \psi_j (2x-1)$$

Table (2) lists the least square errors obtained by running the programs for algorithms (WC, WG and WL) with different values to find approximate solution of above equation.

Tab	le (2)Th	e ap	proxin	nated	valu	es of

#### **Conclusions:**

The approximate solution using two different types of basis function power series functions with the aid of weighted residual methods has been obtained for two examples. Good results were obtained and the following conclusion points are drawn.

1. In terms of the results, Galerkin s method gives more accurate solution than collocation method and least square method, see tables (1)

The good approximation depends on:

The number of the orthogonal polynomials The number of the root  $\circ x_i \circ s$  of the orthogonal polynomials, i.e. as it

increases the L.S.E. approaches to zero.
